

# APPLICATIONS OF GRAPH LAPLACEANS: CLUSTERING

- Details on clustering
- K-means
- Similarity graphs, KNN graphs
- Edge cuts, ratio cuts, etc.
- Application: segmentation

## Clustering: Background

➤ Problem: we are given  $n$  data items:  $x_1, x_2, \dots, x_n$ . Would like to 'cluster' them, i.e., group them so that each group or cluster contains items that are similar in some sense.

➤ Example: materials

➤ Example: Digits

- Refer to each group as a 'cluster' or a 'class'
- A basic method: K-Means

## A basic method: K-means

➤ A basic algorithm that uses Euclidean distance

- 1 Select  $p$  initial centers:  $c_1, c_2, \dots, c_p$  for classes  $1, 2, \dots, p$
- 2 For each  $x_i$  do: determine class of  $x_i$  as  $\text{argmin}_k \|x_i - c_k\|$
- 3 Redefine each  $c_k$  to be the centroid of class  $k$
- 4 Repeat until convergence

- Simple algorithm
- Works well (gives good results) but can be slow
- Performance depends on initialization

## Methods based on similarity graphs

➤ Class of Methods that perform clustering by exploiting a graph that describes the similarities between any two items in the data.

➤ Need to:

1. decide what nodes are in the neighborhood of a given node
2. quantify their similarities - by assigning a weight to any pair of nodes.

**Example:** For text data: Can decide that any columns  $i$  and  $j$  with a cosine greater than 0.95 are 'similar' and assign that cosine value to  $w_{ij}$

## First task: build a 'similarity' graph

- Goal: to build a **similarity** graph, i.e., a graph that captures similarity between any two items

- Two methods: K-nearest Neighbor graphs or use Gaussian ('heat') kernel

10-5

- Clustering

## K-nearest neighbor graphs

- Given: a set of  $n$  data points  $X = \{x_1, \dots, x_n\} \rightarrow$  vertices
- Given: a **proximity** measure between two data points  $x_i$  and  $x_j$  – as measured by a quantity  $dist(x_i, x_j)$
- Want: For each point  $x_i$  a list of the 'nearest neighbors' of  $x_i$  (edges between  $x_i$  and these nodes).
- Note: graph will usually be **directed**  $\rightarrow$  need to symmetrize

10-6

- Clustering

## Nearest neighbor graphs

- For each node, get a few of the nearest neighbors  $\rightarrow$  Graph

- Problem: How to build a nearest-neighbor graph from given data
- We will revisit this later.

10-7

- Clustering

Two types of nearest neighbor graph often used:

**$\epsilon$ -graph:** Edges consist of pairs  $(x_i, x_j)$  such that  $\rho(x_i, x_j) \leq \epsilon$

**$k$ NN graph:** Nodes adjacent to  $x_i$  are those nodes  $x_\ell$  with the  $k$  with smallest distances  $\rho(x_i, x_\ell)$ .

- $\epsilon$ -graph is undirected and is geometrically motivated. Issues: 1) may result in disconnected components 2) what  $\epsilon$ ?
- $k$ NN graphs are directed in general (can be trivially fixed).
- $k$ NN graphs especially useful in practice.

10-8

- Clustering

## Similarity graphs: Using 'heat-kernels'

Define weight between  $i$  and  $j$  as:

$$w_{ij} = f_{ij} \times \begin{cases} e^{-\frac{\|x_i - x_j\|^2}{\sigma_x^2}} & \text{if } \|x_i - x_j\| < r \\ 0 & \text{if not} \end{cases}$$

- Note  $\|x_i - x_j\|$  could be any measure of distance...
- $f_{ij}$  = optional = some measure of similarity - other than distance
- Only nearby points kept.
- Sparsity depends on parameters

10-9

- Clustering

## Edge cuts, ratio cuts, normalized cuts, ...

- Assume now that we have built a 'similarity graph'
- Setting is identical with that of graph partitioning.
- Need a Graph Laplacean:  $L = D - W$  with  $w_{ii} = 0, w_{ij} \geq 0$  and  $D = \text{diag}(W * \text{ones}(n, 1))$  [in matlab notation]

- Partition vertex set  $V$  in two sets  $A$  and  $B$  with

$$A \cup B = V, \quad A \cap B = \emptyset$$

- Define

$$\text{cut}(A, B) = \sum_{u \in A, v \in B} w(u, v)$$

10-10

- Clustering

- First (naive) approach: use this measure to partition graph, i.e., ... Find  $A$  and  $B$  that minimize  $\text{cut}(A, B)$ .
- Issue: Small sets, isolated nodes, big imbalances,

10-11

- Clustering

## Ratio-cuts

- Standard Graph Partitioning approach: Find  $A, B$  by solving

$$\text{Minimize } \text{cut}(A, B), \text{ subject to } |A| = |B|$$

- Condition  $|A| = |B|$  not too meaningful in some applications - too restrictive in others.

- Minimum Ratio Cut approach. Find  $A, B$  by solving:

$$\text{Minimize } \frac{\text{cut}(A, B)}{|A| \cdot |B|}$$

- Difficult to find solution (original paper [Wei-Cheng '91] proposes several heuristics)

- Approximate solution : spectral .

10-12

- Clustering

**Theorem** [Hagen-Kahng, 91] If  $\lambda_2$  is the 2nd smallest eigenvalue of  $L$ , then a lower bound for the cost  $c$  of the optimal ratio cut partition, is:

$$c \geq \frac{\lambda_2}{n}.$$

**Proof:** Consider an optimal partition  $A, B$  and let  $p = |A|/n, q = |B|/n$ . Note that  $p + q = 1$ . Let  $x$  be the vector with coordinates

$$x_i = \begin{cases} q & \text{if } i \in A \\ -p & \text{if } i \in B \end{cases}$$

Note that  $x \perp \mathbf{1}$ . Also if  $(i, j) ==$  an edge-cut then  $|x_i - x_j| = |q - (-p)| = |q + p| = 1$ , otherwise  $x_i - x_j = 0$ . Therefore,  $x^T L x = \sum_{(i,j) \in E} (x_i - x_j)^2 = w(A, B)$ . In addition:

$$\|x\|^2 = pq^2n + qp^2n = pq(p + q)n = pqn = \frac{|A| \cdot |B|}{n}.$$

Therefore, by the Courant-Fischer theorem:

$$\lambda_2 \leq \frac{(Lx, x)}{(x, x)} = n \times \frac{w(A, B)}{|A| \cdot |B|} = n \times c.$$

Hence result. ■

► Idea is to use eigenvector associated with  $\lambda_2$  to determine partition, e.g., based on sign of entries. Use the ratio-cut measure to actually determine where to split.

### Normalized cuts [Shi-Malik, 2000]

► Recall notation  $w(X, Y) = \sum_{x \in X, y \in Y} w(x, y)$  - then define:

$$\text{ncut}(A, B) = \frac{\text{cut}(A, B)}{w(A, V)} + \frac{\text{cut}(A, B)}{w(B, V)}$$

► Goal is to avoid small sets  $A, B$

⚠️ What is  $w(A, V)$  in the case when  $w_{ij} == 1$  ?

► Let  $x$  be an indicator vector:

$$x_i = \begin{cases} 1 & \text{if } i \in A \\ 0 & \text{if } i \in B \end{cases}$$

► Recall that:  $x^T L x = \sum_{(i,j) \in E} w_{ij} |x_i - x_j|^2$  (note: each edge counted once)

► Therefore:

$$\text{cut}(A, B) = \sum_{x_i=1, x_j=0} w_{ij} = x^T L x$$

$$w(A, V) = \sum_{x_i=1} d_i = x^T W \mathbf{1} = x^T D \mathbf{1}$$

$$w(B, V) = \sum_{x_j=0} d_j = (\mathbf{1} - x)^T W \mathbf{1} = (\mathbf{1} - x)^T D \mathbf{1}$$

► Goal now: to minimize ncut

$$\min_{A, B} \text{ncut}(A, B) = \min_{x_i \in \{0,1\}} \frac{x^T L x}{x^T D x} + \frac{x^T L x}{(\mathbf{1} - x)^T D x}$$

➤ Let

$$\beta = \frac{w(A, V)}{w(B, V)} = \frac{x^T D \mathbf{1}}{(\mathbf{1} - x)^T D \mathbf{1}}$$
$$y = x - \beta(\mathbf{1} - x)$$

➤ Then we need to solve:

$$\min_{y_i \in \{0, -\beta\}} \frac{y^T L y}{y^T D y}$$

Subject to  $y^T D \mathbf{1} = 0$

➤ + Relax → need to solve Generalized eigenvalue problem

$$L y = \lambda D y$$

➤  $y_1 = \mathbf{1}$  is eigenvector associated with eigenvalue  $\lambda_1 = 0$

➤  $y_2$  associated with second eigenvalue solves problem.

### A few properties

☞<sub>2</sub> Show that

$$ncut(A, B) = \sigma \times \frac{cut(A, B)}{w(A, V) \times w(B, V)}$$

where  $\sigma$  is a constant

☞<sub>3</sub> How do ratio-cuts and normalized cuts compare when the graph is  $d$ -regular (same degree for each node).

### Extension to more than 2 clusters

➤ Just like graph partitioning we can:

1. Apply the method recursively [Repeat clustering on the resulted parts]
2. or compute a few eigenvectors and run K-means clustering on these eigenvectors to get the clustering.

### Application: Image segmentation

- First task: obtain a graph from pixels.
- Common idea: use “Heat kernels”
- Let  $F_j$  = feature value (e.g., brightness), and Let  $X_j$  = spatial position.

Then define

$$w_{ij} = e^{-\frac{\|F_i - F_j\|^2}{\sigma_f^2}} \times \begin{cases} e^{-\frac{\|X_i - X_j\|^2}{\sigma_x^2}} & \text{if } \|X_i - X_j\| < r \\ 0 & \text{else} \end{cases}$$

- Sparsity depends on parameters

## Spectral clustering: General approach

- 1 Given: Collection of data samples  $\{x_1, x_2, \dots, x_n\}$
- 2 Build a **similarity** graph between items

- 3 Compute (smallest) eigenvector ( $s$ ) of resulting graph Laplacean
  - 4 Use k-means on eigenvector ( $s$ ) of Laplacean
- For Normalized cuts solve generalized eigen problem.

10-21

- Clustering

- Alg. Multiplicity of eigenvalue zero = # connected components.

10-22

- Clustering

## Building a nearest neighbor graph

- Question: How to build a nearest-neighbor graph from given data?

- Will demonstrate the power of a divide a conquer approach combined with the Lanczos algorithm.
- Note: The Lanczos algorithm will be covered in detail later

10-23

- knn

Recall: Two common types of nearest neighbor graphs

**$\epsilon$ -graph:** Edges consist of pairs  $(x_i, x_j)$  such that  $\rho(x_i, x_j) \leq \epsilon$

**$k$ NN graph:** Nodes adjacent to  $x_i$  are those nodes  $x_\ell$  with the  $k$  with smallest distances  $\rho(x_i, x_\ell)$ .

- $\epsilon$ -graph is undirected and is geometrically motivated. Issues: 1) may result in disconnected components 2) what  $\epsilon$ ?
- $k$ NN graphs are directed in general (can be trivially fixed).
- $k$ NN graphs especially useful in practice.

10-24

- knn

## Divide and conquer KNN: key ingredient

- Key ingredient is *Spectral bisection*
- Let the data matrix  $\mathbf{X} = [\mathbf{x}_1, \dots, \mathbf{x}_n] \in \mathbb{R}^{d \times n}$
- Each column == a data point.
- Center the data:  $\hat{\mathbf{X}} = [\hat{\mathbf{x}}_1, \dots, \hat{\mathbf{x}}_n] = \mathbf{X} - \mathbf{c}\mathbf{e}^T$   
where  $\mathbf{c}$  == centroid;  $\mathbf{e} = \mathbf{ones}(d, 1)$  (matlab)

**Goal:** Split  $\hat{\mathbf{X}}$  into halves using a hyperplane.

**Method:** Principal Direction Divisive Partitioning D. Boley, '98.

**Idea:** Use the  $(\sigma, \mathbf{u}, \mathbf{v})$  = largest singular triplet of  $\hat{\mathbf{X}}$  with:

$$\mathbf{u}^T \hat{\mathbf{X}} = \sigma \mathbf{v}^T.$$

10-25

- knn

- Hyperplane is defined as  $\langle \mathbf{u}, \mathbf{x} \rangle = 0$ , i.e., it splits the set of data points into two subsets:

$$\mathbf{X}_+ = \{\mathbf{x}_i \mid \mathbf{u}^T \hat{\mathbf{x}}_i \geq 0\} \quad \text{and} \quad \mathbf{X}_- = \{\mathbf{x}_i \mid \mathbf{u}^T \hat{\mathbf{x}}_i < 0\}.$$

- Note that  $\mathbf{u}^T \hat{\mathbf{x}}_i = \mathbf{u}^T \hat{\mathbf{X}} \mathbf{e}_i = \sigma \mathbf{v}^T \mathbf{e}_i \rightarrow$

10-26

- knn

$$\mathbf{X}_+ = \{\mathbf{x}_i \mid v_i \geq 0\} \quad \text{and} \quad \mathbf{X}_- = \{\mathbf{x}_i \mid v_i < 0\},$$

where  $v_i$  is the  $i$ -th entry of  $\mathbf{v}$ .

- In practice: replace above criterion by

$$\mathbf{X}_+ = \{\mathbf{x}_i \mid v_i \geq \text{med}(\mathbf{v})\} \quad \& \quad \mathbf{X}_- = \{\mathbf{x}_i \mid v_i < \text{med}(\mathbf{v})\}$$

where  $\text{med}(\mathbf{v})$  == median of the entries of  $\mathbf{v}$ .

- For largest singular triplet  $(\sigma, \mathbf{u}, \mathbf{v})$  of  $\hat{\mathbf{X}}$ : use Golub-Kahan-Lanczos algorithm or Lanczos applied to  $\hat{\mathbf{X}}\hat{\mathbf{X}}^T$  or  $\hat{\mathbf{X}}^T\hat{\mathbf{X}}$
- Cost (assuming  $s$  Lanczos steps):  $O(n \times d \times s)$ ; Usually:  $d$  very small

10-27

- knn

## Two divide and conquer algorithms

**Overlap method:** divide current set into two overlapping subsets  $\mathbf{X}_1, \mathbf{X}_2$

**Glue method:** divide current set into two disjoint subsets  $\mathbf{X}_1, \mathbf{X}_2$  plus a third set  $\mathbf{X}_3$  called gluing set.

10-28

- knn

## The Overlap Method

➤ Divide current set  $X$  into two overlapping subsets:

$$X_1 = \{x_i \mid v_i \geq -h_\alpha(S_v)\} \quad \text{and} \quad X_2 = \{x_i \mid v_i < h_\alpha(S_v)\},$$

- where  $S_v = \{|v_i| \mid i = 1, 2, \dots, n\}$ .
- and  $h_\alpha(\cdot)$  is a function that returns an element larger than  $(100\alpha)\%$  of those in  $S_v$ .

➤ Rationale: to ensure that the two subsets overlap  $(100\alpha)\%$  of the data, i.e.,

$$|X_1 \cap X_2| = \lceil \alpha |X| \rceil.$$

## The Glue Method

Divide the set  $X$  into two disjoint subsets  $X_1$  and  $X_2$  with a gluing subset  $X_3$ :

$$X_1 \cup X_2 = X, \quad X_1 \cap X_2 = \emptyset, \quad X_1 \cap X_3 \neq \emptyset, \quad X_2 \cap X_3 \neq \emptyset.$$

Criterion used for splitting:

$$X_1 = \{x_i \mid v_i \geq 0\}, \quad X_2 = \{x_i \mid v_i < 0\}, \\ X_3 = \{x_i \mid -h_\alpha(S_v) \leq v_i < h_\alpha(S_v)\}.$$

Note: gluing subset  $X_3$  here is just the intersection of the sets  $X_1, X_2$  of the overlap method.

## Approximate $k$ NN Graph Construction: The Overlap Method

```
function  $G = k$ NN-Overlap[ $X, k, \alpha$ ]  
  if  $|X| < n_k$   
     $G \leftarrow$  Call  $k$ NN-BruteForce[ $X, k$ ]  
  else  
     $(X_1, X_2) \leftarrow$  Call Divide-Overlap[ $X, \alpha$ ]  
     $G_1 \leftarrow$  Call  $k$ NN-Overlap[ $X_1, k, \alpha$ ]  
     $G_2 \leftarrow$  Call  $k$ NN-Overlap[ $X_2, k, \alpha$ ]  
     $G \leftarrow$  Call Conquer[ $G_1, G_2$ ]  
    Call Refine[ $G$ ]  
  EndIf  
End
```

## Approximate $k$ NN Graph Construction: The Glue Method

```
function  $G = k$ NN-Glue[ $X, k, \alpha$ ]  
  if  $|X| < n_k$   
     $G \leftarrow$  Call  $k$ NN-BruteForce[ $X, k$ ]  
  else  
     $(X_1, X_2, X_3) \leftarrow$  Call Divide-Glue[ $X, \alpha$ ]  
     $G_1 \leftarrow$  Call  $k$ NN-Glue[ $X_1, k, \alpha$ ]  
     $G_2 \leftarrow$  Call  $k$ NN-Glue[ $X_2, k, \alpha$ ]  
     $G_3 \leftarrow$  Call  $k$ NN-Glue[ $X_3, k, \alpha$ ]  
     $G \leftarrow$  Call Conquer[ $G_1, G_2, G_3$ ]  
    Call Refine[ $G$ ]  
  EndIf  
End
```

**Theorem** The time complexity for the overlap method is

$$T_o(n) = \Theta(dn^{t_o}),$$

where:  $t_o = \log_{2/(1+\alpha)} 2 = \frac{1}{1 - \log_2(1 + \alpha)}$ .

**Theorem** The time complexity for the glue method is

$$T_g(n) = \Theta(dn^{t_g}/\alpha),$$

where  $t_g$  is the solution to the equation:  $\frac{2}{2^t} + \alpha^t = 1$ .

**Example:** When  $\alpha = 0.1$ , then  $t_o = 1.16$  while  $t_g = 1.12$ .
